The dopamine transporter (also dopamine active transporter, DAT, SLC6A3) is a membrane-spanning protein that pumps the neurotransmitter dopamine out of the synaptic cleft back into cytosol. In the cytosol, other transporters sequester the dopamine into vesicles for storage and later release.

Dopamine transporter — Wikipedia

Dopamine receptors are the areas of the brain that accept the message delivered via the dopamine system and ended by the dopamine transporters. Certain neurons are sensitive to dopamine, and these are the ones that receive the dopamine transmissions. What Are Dopamine Transporters? Dopamine transporter is a protein existing between the neurons in the brain.

At that time, the only possible approaches were neuroanatomy with histochemical techniques, analytical chemistry of the transmitter and its metabolites, and pharmacology of the receptors and transporters. In particular, dopamine receptors were thought of as basically operational entities necessary to account for dopamine action and its quantification, based on the effects of agonists and antagonists.

Dopamine receptors and transporters : function, imaging —

The dopamine transporter (DAT) is a transmembrane protein that is responsible for the reuptake of dopamine (DA) from the synaptic cleft and for the termination of dopaminergic transmission. The DAT is a target of several drugs, including psychostimulants, such as amphetamine and cocaine, and is also subject to short- and long-term regulation by several drugs and mechanisms.

Dopamine: Functions, Signaling, and Association with —

Inside the brain, dopamine functions as a neurotransmitter and neuromodulator, and is controlled by a set of mechanisms common to all monoamine neurotransmitters. After synthesis, dopamine is transported from the cytosol into synaptic vesicles by a solute carrier (a vesicular monoamine transporter, VMAT2).

Extracellular dopamine is regulated by dopamine transporters (DAT) and vesicular monoamine transporters-2 (VMAT2), translocating dopamine across plasmalemma and synaptic vesicular membrane, respectively. 17 DAT-deficient mice exhibit increased extracellular dopamine and greater food intake compared with wild-type mice. 18 Genetic-linkage analysis reveals human DAT gene polymorphisms with a greater frequency of short alleles associated with decreased DAT expression and binge eating. 19 Thus ...

This study was designed to examine the effects of acute and chronic METH exposure on uptake and release of [3H]dopamine (DA) in cultured midbrain dopamine neurons to determine if persistent neuronal adaptations ensue. In addition, we have assessed DA D2 receptor function to determine if chronic METH alters this receptor.
