An advanced ECT technique for weld inspection, eddy current array (ECA) for weld inspection makes it possible to detect small cracks, inclusions, and other flaws that are unlikely to be detected in other ways. This allows for a greater level of assurance in the quality and reliability of the welds that quite literally hold the world together.

Understanding the Use of Eddy Current for Weld Inspection ...

The Eddy Current Testing (ECT) Weld Probe Inspection Procedure requires a certain workflow of scanning in accordance to the standard BS EN 1711 now superseded by ISO 17643 (Non-destructive examination of welds - Eddy current examination of welds by complex plane analysis). More information on this standard can be found at the BSi Website.

How to inspect with an EC Weld Probe - Eddy Current

Eddy Current Weld Inspection The Importance of Weld Inspection The quality of welds is becoming increasingly important as customer expectations rise. Products and components are expected to be of a high quality and not to fail unexpectedly.

The uniform eddy current probe Type 2 is applied to inspection of the weld zone inducing the eddy current parallel to the weld line as shown in Figure 3 (b). Two detector coils are connected for the differential, thus the probe has very little noise from weld zone.

Eddy current testing is one of several non-destructive testing methods that uses the electromagnetism principle for flaw detection in conductive materials. A specially designed coil energised with an alternating-current is placed in proximity to the test surface, generating a changing magnetic field that interacts with the test-part and produces eddy currents in the vicinity.

Eddy Current Testing - A Definitive Guide - TWI

Eddy-current testing (also commonly seen as eddy current testing and ECT) is one of many electromagnetic testing methods used in nondestructive testing (NDT) making use of electromagnetic induction to detect and characterize surface and sub-surface flaws in conductive materials.

Eddy-current testing - Wikipedia

Non Destructive Testing (NDT) and Eddy Current Testing from TIS-UK Technical Inspection Services (UK) Ltd has been providing Non Destructive Testing for the past 32 years to major industries including nuclear power, aerospace, shipping and construction.

Non Destructive testing and eddy current testing

The operating principle of ET detectors is based on the eddy current method, which consists in the distortion of eddy currents in the local test zone, followed by recording the changes in the electromagnetic field of the eddy currents that are caused by the defect and the electrophysical properties of the test object. This method is characterized by small test depths, as it is used to detect cracks and discontinuities in the material at a depth up to 2 mm.

Welds testing - OKOndt

Conventional eddy current testing utilises electromagnetic induction to detect discontinuities in conductive materials. A specially designed coil energised with alternating current is placed in proximity to the test surface generating changing magnetic-field which interacts with the test-part producing eddy current in the vicinity.
